[57] **ABSTRACT**

An automated system and method detects fraudulent transactions using a predictive model such as a neural network to evaluate individual customer accounts and identify potentially fraudulent transactions based on learned relationships among known variables. The system may also output reason codes indicating relative contributions of various variables to a particular result. The system periodically monitors its performance and redevelops the model when performance drops below a predetermined level.

The screenshot shows a window titled "Account Score". At the top, it displays "Account 4400613000006130" and "Name Sandra Simpson". Below this, the "Score" is 966. A section titled "Reasons" lists three items: "1 Suspicious approve/decline pattern", "2 Suspicious recent transaction rate", and "3 Suspicious previous day transaction activity". Below the reasons, there is a section for "Current and Previous 7 days" with a sub-header "Auth Records". This section contains two tables of transaction data. The first table is for the "Last 6 months" and the second is for the "Last 6 months" (labeled as such in the image). Both tables have columns for Tran Amt, Date, Time, Avcred, CredLim, Sic, Merch, and Zip. The first table has 6 rows of data, and the second table has 6 rows of data. At the bottom of the window, there are "OK" and "Help" buttons.

FRAUD DETECTION USING PREDICTIVE MODELING

CROSS-REFERENCE TO RELATED APPLICATION

U.S. application Ser. No. 07/814,179, (attorney's docket number 726) for "Neural Network Having Expert System Functionality", by Curt A. Levey, filed Dec. 30, 1991.

BACKGROUND OF THE INVENTION

1. Field of the Invention

This invention relates generally to the detection of fraudulent use of customer accounts and account numbers, including for example credit card transactions. In particular, the invention relates to an automated fraud detection system and method that uses predictive modeling to perform pattern recognition and classification in order to isolate transactions having high probabilities of fraud.

2. Description of the Related Art

In the following discussion, the term "credit card" will be used for illustrative purposes; however, the techniques and principles discussed herein apply to other types of customer accounts, such as charge cards, bank automated teller machine cards and telephone calling cards.

Credit card issuers conventionally attempt to limit fraud losses by immediately closing a customer's account upon receiving a report that the card has been lost or stolen. Typically, the customer's credit information is then transferred to a new account and a new card is issued. This procedure is only effective in limiting fraudulent use of lost or stolen cards after the loss or theft has been reported to the issuer.

In many cases, however, fraudulent use occurs without the knowledge of the cardholder, and therefore no report is made to the issuer. This may occur if the customer is unaware that the card has been lost or stolen, or if other techniques are employed to perpetrate the fraud, such as: use of counterfeit cards; merchant fraud; application fraud; or interception of credit cards in the mail. In all these situations, the fraudulent use may not be detected until (and unless) the cardholder notices an unfamiliar transaction on his or her next monthly statement and contests the corresponding charge. The concomitant delay in detection of fraud may result in significant losses. User fraud, in which the user claims that a valid transaction is invalid, is also possible.

Issuers of credit cards have sought to limit fraud losses by attempting to detect fraudulent use before the cardholder has reported a lost or stolen card. One conventional technique is known as parameter analysis. A parameter analysis fraud detection scheme makes a decision using a small number of database fields combined in a simple Boolean condition. An example of such a condition is:

if (number of transactions in 24 hours>X) and (more than Y dollars authorized) then flag this account as high risk

Parameter analysis will provide the values of X and Y that satisfy either the required detection rate or the required false positive rate. In a hypothetical example, parameter values of X=400 and Y=1000 might capture 20% of the frauds with a false positive rate of 200:1, while X=6 and Y=2000 might capture 8% of the frauds with a false positive rate of 20:1.

The rules that parameter analysis provides are easily implemented in a database management system, as they are restricted to Boolean (e.g., and, or) combinations of conditions on single variables.

Parameter analysis derives rules by examining the single variables most able to distinguish fraudulent from non-fraudulent behavior. Since only single-variable threshold comparisons are used, complex interactions among variables are not captured. This is a limitation that could cause the system to discriminate poorly between fraudulent and valid account behavior, resulting in low capture rates and high false-positive rates.

Additionally, an effective fraud detection model generally requires more variables than conventional parameter analysis systems can handle. Furthermore, in order to capture new fraud schemes, parameter analysis systems must be redeveloped often, and automated redevelopment is difficult to implement.

It is desirable, therefore, to have an automated system that uses available information regarding cardholders, merchants, and transactions to screen transactions and isolate those which are likely to be fraudulent, and which captures a relatively high proportion of frauds while maintaining a relatively low false-positive rate. Preferably, such a system should be able to handle a large number of interdependent variables, and should have capability for redevelopment of the underlying system model as new patterns of fraudulent behavior emerge.

SUMMARY OF THE INVENTION

In accordance with the present invention, there is provided an automated system and method for detecting fraudulent transactions, which uses a predictive model such as a neural network to evaluate individual customer accounts and identify potentially fraudulent transactions based on learned relationships among known variables. These relationships enable the system to estimate a probability of fraud for each transaction. This probability may then be provided as output to a human decision-maker involved in processing the transaction, or the issuer may be signaled when the probability exceeds a predetermined amount. The system may also output reason codes that reveal the relative contributions of various factors to a particular result. Finally, the system periodically monitors its performance, and redevelops the model when performance drops below a predetermined level.

BRIEF DESCRIPTION OF THE DRAWINGS

FIG. 1 is a block diagram of an implementation of the present invention.

FIG. 2 is a sample system monitor screen which forms part of a typical output interface for the present invention.

FIG. 3 is a sample account selection screen which forms part of a typical output interface for the present invention.

FIG. 4 is a sample transaction analysis screen which forms part of a typical output interface for the present invention.

FIG. 5 is a sample customer information screen which forms part of a typical output interface for the present invention.

FIG. 6 is a sample analyst response screen which forms part of a typical output interface for the present invention.

DESCRIPTION OF THE PREFERRED EMBODIMENT

The Figures depict preferred embodiments of the present invention for purposes of illustration only. One skilled in the art will readily recognize from the following discussion that alternative embodiments of the structures and methods illustrated herein may be employed without departing from the principles of the invention described herein.

Referring now to FIG. 1, there is shown a block diagram of a typical implementation of a system 100 in accordance with the present invention. Transaction information is applied to system 100 via data network 105, which is connected to a conventional financial data facility 106 collecting transaction information from conventional sources such as human-operated credit-card authorization terminals and automated teller machines (not shown). CPU 101 runs software program instructions, stored in program storage 107, which direct CPU 101 to perform the various functions of the system. In the preferred embodiment, the software program is written in the ANSI C language, which may be run on a variety of conventional hardware platforms. In accordance with the software program instructions, CPU 101 stores the data obtained from data network 105 in data storage 103, and uses RAM 102 in a conventional manner as a workspace. CPU 101, data storage 103, and program storage 107 operate together to provide a neural network model 108 for predicting fraud. After neural network 108 processes the information, as described below, to obtain an indication of the likelihood of fraud, a signal indicative of that likelihood is sent from CPU 101 to output device 104.

In the preferred embodiment, CPU 101 is a Model 3090 IBM mainframe computer, RAM 102 and data storage 103 are conventional RAM, ROM and disk storage devices for the Model 3090 CPU, and output device 104 is a conventional means for either printing results based on the signals generated by neural network 108, or displaying the results on a video screen using a window-based interface system, or sending the results to a database for later access, or sending a signal dependent on the results to an authorization system (not shown) for further processing.

Referring now also to FIGS. 2 through 6, there are shown sample screens from a conventional window-based interface

system (not shown) which forms part of output device 104. FIG. 2 shows system monitor 201 that allows a fraud analyst or system supervisor to review system performance. System monitor 201 shows a cutoff score 202 above which accounts will be flagged, the number of accounts with scores above the cutoff 203, and the fraud score 204 and account number 205 for a particular account.

FIG. 3 shows account selection screen 301 that includes a scrolling window 302 allowing the analyst to select high-risk transactions for review, and a set of buttons 303 allowing the analyst to select further operations in connection with the selected transactions.

FIG. 4 shows transaction analysis screen 401 that allows the fraud analyst to examine each high-risk transaction and determine appropriate fraud control actions. It includes account information 402, fraud score 403, explanations derived from reason codes 404 that indicate the reasons for fraud score 403, and two scrolling windows 405 and 406 that show transaction information for the current day and the past seven days 405, and for the past six months 406.

FIG. 5 shows customer information screen 501 that allows the analyst to access customer information, including account number 502, customer names 503, best time to call 504, phone numbers 505, and address 506. It also provides access to further functions via on-screen buttons 507.

FIG. 6 shows analyst response screen 601 that allows the analyst to log actions taken to control fraud. It includes a series of check boxes 602 for logging information, a comment box 603, and on-screen buttons 604 allowing access to other functions.

Referring now also to FIG. 7, there is shown an overall flowchart illustrating the major functions and operation of the system 100. First neural network model 108 is trained 701 using data describing past transactions from data network 105. Then data describing the network model are stored 702. Once the model description is stored, system 100 is able to process current transactions. System 100 obtains data for a current transaction 703, and applies the current transaction data to the stored network model 704. The model 108 determines a fraud score and reason codes (described below), which are output 705 to the user, or to a database, or to another system via output device 104.

Referring now to FIG. 8, the overall functional architecture of system 100 is shown. System 100 is broken down into two major components: model development component 801 and transaction processing component 802. Model development component 801 uses past data 804 to build neural network 108 containing information representing learned relationships among a number of variables. Together, the learned relationships form a model of the behavior of the variables. Although a neural network is used in the preferred embodiment, any type of predictive modeling technique may be used. For purposes of illustration, the invention is described here in terms of a neural network.

Transaction processing component 802 performs three functions: 1) it determines the likelihood of fraud for each transaction by feeding data from various sources 805, 806 into neural network 108, obtaining results, and outputting them 807; 2) when applicable, it creates a record in a profile database 806 summarizing past transactional patterns of the customer; and 3) when applicable, it updates the appropriate record in profile database 806.

Each of the two components of the system will be described in turn.

Model Development Component 801

Neural Networks: Neural networks employ a technique of "learning" relationships through repeated exposure to data

and adjustment of internal weights. They allow rapid model development and automated data analysis. Essentially, such networks represent a statistical modeling technique that is capable of building models from data containing both linear and non-linear relationships. While similar in concept to regression analysis, neural networks are able to capture nonlinearity and interactions among independent variables without pre-specification. In other words, while traditional regression analysis requires that nonlinearities and interactions be detected and specified manually, neural networks perform these tasks automatically. For a more detailed description of neural networks, see D. E. Rumelhart et al, "Learning Representations by Back-Propagating Errors", *Nature* v. 323, pp. 533-36 (1986), and R. Hecht-Nielsen, "Theory of the Backpropagation Neural Network", in *Neural Networks for Perception*, pp. 65-93 (1992), the teachings of which are incorporated herein by reference.

Neural networks comprise a number of interconnected neuron-like processing elements that send data to each other along connections. The strengths of the connections among the processing elements are represented by weights. Referring now to FIG. 9, there is shown a diagram of a single processing element 901. The processing element receives inputs X_1, X_2, \dots, X_n , either from other processing elements or directly from inputs to the system. It multiplies each of its inputs by a corresponding weight w_1, w_2, \dots, w_n , and adds the results together to form a weighted sum 902. It then applies a transfer function 903 (which is typically non-linear) to the weighted sum, to obtain a value Z known as the state of the element. The state Z is then either passed on to another element along a weighted connection, or provided as an output signal. Collectively, states are used to represent information in the short term, while weights represent long-term information or learning.

Processing elements in a neural network can be grouped into three categories: input processing elements (those which receive input data values); output processing elements (those which produce output values); and hidden processing elements (all others). The purpose of hidden processing elements is to allow the neural network to build intermediate representations that combine input data in ways that help the model learn the desired mapping with greater accuracy. Referring now to FIG. 10, there is shown a diagram illustrating the concept of hidden processing elements. Inputs 1001 are supplied to a layer of input processing elements 1002. The outputs of the input elements are passed to a layer of hidden elements 1003. Typically there are several such layers of hidden elements. Eventually, hidden elements pass outputs to a layer of output elements 1004, and the output elements produce output values 1005.

Neural networks learn from examples by modifying their weights. The "training" process, the general techniques of which are well known in the art, involves the following steps:

- 1) Repeatedly presenting examples of a particular input/output task to the neural network model;
- 2) Comparing the model output and desired output to measure error; and
- 3) Modifying model weights to reduce the error.

This set of steps is repeated until further iteration fails to decrease the error. Then, the network is said to be "trained." Once training is completed, the network can predict outcomes for new data inputs.

Fraud-Related Variables: In the present invention, data used to train the model are drawn from various database files containing historical data on individual transactions, merchants, and customers. These data are preferably pre-

processed before being fed into the neural network, resulting in the creation of a set of fraud-related variables that have been empirically determined to form more effective predictors of fraud than the original historical data.

Referring now to FIG. 11, there is shown a flowchart of the pre-processing method of the present invention. Individual elements of the flowchart are indicated by designations which correspond to module names. The following brief description summarizes the processing.

Data used for pre-processing is taken from three databases which contain past data: 1) past transaction database 1101 (also called an "authorization database") containing two years' worth of past transaction data, which may be implemented in the same data base as past data 804; 2) customer database 1103 containing customer data; and 3) fraud database 1102 which indicates which accounts had fraudulent activity and when the fraudulent activity occurred.

Module readauth.sas 1104 reads transaction data from past transaction database 1101. Module matchauth.sas 1105 samples this transaction data to obtain a new transaction data set containing all of the fraud accounts and a randomly-selected subset of the non-fraud accounts. In creating the new transaction data set, module matchauth.sas 1105 uses information from fraud database 1102 to determine which accounts have fraud and which do not. For effective network training, it has been found preferable to obtain approximately ten non-fraud accounts for every fraud account.

Module readex.sas 1106 reads customer data from customer database 1103. Module matchex.sas 1107 samples this customer data to obtain a new customer data set containing all of the fraud accounts and the same subset of non-fraud accounts as was obtained by module matchauth.sas. In creating the new customer data set, module matchex.sas 1107 uses information from fraud database 1102 to determine which accounts have fraud and which do not.

Module mxmerge.sas 1108 merges all of the data sets obtained by modules matchauth.sas 1105 and matchex.sas 1107. Module genau.sas 1109 subdivides the merged data set into subsets of monthly data.

Module gensamp.sas 1112 samples the data set created by module mxmerge.sas 1108 and subdivided by genau.sas 1109, and creates a new data set called sample.ssd where each record represents a particular account on a particular day with transaction activity. Module gensamp.sas 1112 determines which records are fraudulent using information from fraud database 1102. Module gensamp.sas 1112 provides a subset of authorization days, as follows: From the database of all transactions, a set of active account-days is created by removing multiple transactions for the same customer on the same day. In the set of active account-days, each account day is assigned a "draft number" from 0 to 1. This draft number is assigned as follows: If the account-day is non-fraudulent, then the draft number is set to a random number between 0 and 1. If the account-day is fraudulent and it lies on the first or second day of fraud, then the draft number is set to 0. Otherwise, it is set to 1. Then, the 25,000 account-days with the smallest draft numbers are selected for inclusion in sample.ssd. Thus, all fraudulent account-days (up to 25,000) plus a sample of non-fraudulent account-days are included in sample.ssd.

Module roll15.sas 1113 generates a 15-day rolling window of data. This data has multiple records for each account-day listed in sample.ssd. The current day and 14 preceding days are listed for each sample account.

Module roll15to7.sas 1117 takes the roll15 data set and filters out days eight to 15 to produce roll7, a 7-day rolling window data set 1119. Days eight to 15 are ignored. Module

genroly.sas 1118 generates input variables for a rolling window of the previous 15 days of transactions. It processes a data set with multiple and variable numbers of records per account and produces a data set with one record per account. The result is called rollv.ssd.

Module roll15to1.sas 1114 takes the roll15 data set and filters out days except the current day to produce roll1. Module gencurv.sas 1115 uses roll1 to generate current day variables 1116 describing transactions occurring during the current day.

Module genprof.sas generates profile variables which form the profile records 1111.

Module merge.sas 1120 combines the profile records 1111, 1-day variables 1116, and 7-day variables 1119 and generates new fraud-related variables, as listed below, from the combination. It also merges rollv.ssd with the sample-filtered profile data sets to produce a single data set with both profile and rolling window variables: The result is called the mod1n2 data set 1121 (also called the "training set"), which contains the fraud-related variables needed to train the network. Scaler module 1122 scales the variables such that the mean value for each variable in the scaled training set is 0.0 and the standard deviation is 1.0, to create scaled mod1n2 data set 1123.

Many fraud-related variables may be generated using variations of the pre-processing method described above. Fraud-related variables used in the preferred embodiment include:

Customer usage pattern profiles representing time-of-day and day-of-week profiles;

Expiration date for the credit card;

Dollar amount spent in each SIC (Standard Industrial Classification) merchant group category during the current day;

Percentage of dollars spent by a customer in each SIC merchant group category during the current day;

Number of transactions in each SIC merchant group category during the current day;

Percentage of number of transactions in each SIC merchant group category during the current day;

Categorization of SIC merchant group categories by fraud rate (high, medium, or low risk);

Categorization of SIC merchant group categories by customer types (groups of customers that most frequently use certain SIC categories);

Categorization of geographic regions by fraud rate (high, medium, or low risk);

Categorization of geographic regions by customer types;

Mean number of days between transactions;

Variance of number of days between transactions;

Mean time between transactions in one day;

Variance of time between transactions in one day;

Number of multiple transaction declines at same merchant;

Number of out-of-state transactions;

Mean number of transaction declines;

Year-to-date high balance;

Transaction amount;

Transaction date and time;

Transaction type.

Additional fraud-related variables which may also be considered are listed below:

Current Day Cardholder Fraud Related Variables

bweekend	current day boolean indicating current datetime considered weekend
cavapvdl	current day mean dollar amount for an approval
cavapvdl	current day mean dollar amount for an approval
cavaucl	current day mean dollars per auth across day
ccoscdoni	current day cosine of the day of month i.e. $\cos(\text{day}((\text{datepart}(\text{cst_dt}) * \text{TWOPF}/30))$;
ccoscdow	current day cosine of the day of week i.e. $\cos(\text{weekday}((\text{datepart}(\text{cst_dt}) * \text{TWOPF}/7))$;
ccoscmoy	current day cosine of the month of year i.e. $\cos(\text{month}((\text{datepart}(\text{cst_dt}) * \text{TWOPF}/12))$;
cdom	current day day of month
cdow	current day day of week
chdzip	current cardholder zip
chibal	current day high balance
chidcapv	current day highest dollar amt on a single cash approve
chidcdec	current day highest dollar amt on a single cash decline
chidmapv	current day highest dollar amt on a single merch approve
chidmdec	current day highest dollar amt on a single merch decline
chidsapv	current day highest dollar amount on a single approve
chidsau	current day highest dollar amount on a single auth
chidsdec	current day highest dollar amount on a single decline
cmoy	current day month of year
cratdcau	current day ratio of declines to auths
csincdom	current day sine of the day of month i.e. $\sin(\text{day}((\text{datepart}(\text{cst_dt}) * \text{TWOPF}/30))$;
csincdow	current day sine of the day of week i.e. $\sin(\text{weekday}((\text{datepart}(\text{cst_dt}) * \text{TWOPF}/7))$;
csincmoy	current day sine of the month of year i.e. $\sin(\text{month}((\text{datepart}(\text{cst_dt}) * \text{TWOPF}/12))$;
cst_dt	current day cst datetime derived from zip code and CST auth time
ctdapv	current day total dollars of approvals
ctdau	current day total dollars of auths
ctdcsapv	current day total dollars of cash advance approvals
ctdcsdec	current day total dollars of cash advance declines
ctddec	current day total dollars of declines
ctdmrapv	current day total dollars of merchandise approvals
ctdmrdec	current day total dollars of merchandise declines
ctnapv	current day total number of approves
ctnau	current day total number of auths
ctnau10d	current day number of auths in day <=\$10

-continued

ctnaudy	current day total number of auths in a day
ctncsapv	current day total number of cash advance approvals
ctncsapv	current day total number of cash approves
ctncsdec	current day total number of cash advance declines
ctndec	current day total number of declines
ctmrapv	current day total number of merchandise approvals
ctmurdec	current day total number of merchandise declines
ctnsdapv	current day total number of approvals on the same day of week as current day
ctawdaft	current day total number of weekday afternoon approvals
ctawdapv	current day total number of weekday approvals
ctawdeve	current day total number of weekday evening approvals
ctawdmor	current day total number of weekday morning approvals
ctawdnit	current day total number of weekday night approvals
ctaweafi	current day total number of weekend afternoon approvals
ctaweapv	current day total number of weekend approvals
ctawe eve	current day total number of weekend evening approvals
ctawemor	current day total number of weekend morning approvals
ctawenit	current day total number of weekend night approvals
curbal	current day current balance
cvraud1	current day variance of dollars per auth across day
czrate1	current day zip risk group 1 'Zip very high fraud rate'
czrate2	current day zip risk group 2 'Zip high fraud rate'
czrate3	current day zip risk group 3 'Zip medium high fraud rate'
czrate4	current day zip risk group 4 'Zip medium fraud rate'
czrate5	current day zip risk group 5 'Zip medium low fraud rate'
czrate6	current day zip risk group 6 'Zip low fraud rate'
czrate7	current day zip risk group 7 'Zip very low fraud rate'
czrate8	current day zip risk group 8 'Zip unknown fraud rate'
ctdsfa01	current day total dollars of transactions in SIC factor group 01
ctdsfa02	current day total dollars of transactions in SIC factor group 02
ctdsfa03	current day total dollars of transactions in SIC factor group 03
ctdsfa04	current day total dollars of transactions in SIC factor group 04

pvdabytwn	profile variance in number of days between trx's (min of 3 trx)
pvtadul	profile variance of dollars per auth across month
<u>MERCHANT FRAUD VARIABLES</u>	
mtotturn	Merchant Total turnover for this specific merchant
msicturn	Merchant Cumulative SIC code turnover
mctrage	Merchant Contract age for specific merchant
maagpic	Merchant Average contract age for this SIC code
mavgnbtc	Merchant Average number of transactions in a batch
maamttrx	Merchant Average amount per transaction (average amount per authorizations)
mvarant	Merchant Variance of amount per transaction
mavgbtc	Merchant Average time between batches
mavgtaut	Merchant Average time between authorizations for this merchant
mratks	Merchant Ratio of keyed versus swiped transactions
mnidclac	Merchant Number of identical customer accounts
mnidcham	Merchant Number of identical change amounts
mtxrsrc	Merchant What is the source of transaction (ATM, merchant, etc.)
mtxtsrp	Merchant How is the transaction transported to the source (terminal, non-terminal, voice authorization)
mfloor	Merchant Floor limit
mchgbks	Merchant Charge-backs received
mrtrvs	Merchant Retrievals received (per SIC, merchant, etc.). The issuer pays for a retrieval.
macqrat	Merchant Acquirer risk management rate (in Europe one merchant can have multiple acquires, but they don't have records about how many or who.)
mprevrisk	Merchant Previous risk management at this merchant? Yes or No
mtyprisk	Merchant Type of previous risk management (counterfeit, multiple imprint, lost/stolen/not received)
msicrat	Merchant SIC risk management rate
mpctaut	Merchant Percent of transactions authorized

Network Training: Once pre-processing is complete, the fraud-related variables are fed to the network and the network is trained. The preferred embodiment uses a modeling technique known as a "feed forward" neural network. This type of network estimates parameters which define relationships among variables using a training method. The preferred training method, well known to those skilled in the art, is called "backpropagation gradient descent optimization", although other well-known neural network training techniques may also be used.

One problem with neural networks built with conventional backpropagation methods is insufficient generalizabil-

ity. Generalizability is a measure of the predictive value of a neural network. The attempt to maximize generalizability can be interpreted as choosing a network model with enough complexity so as not to underfit the data but not too much complexity so as to overfit the data. One measure of the complexity of a network is the number of hidden processing elements, so that the effort to maximize generalizability translates into a selection among models having different numbers of hidden processing elements. Unfortunately, it is often not possible to obtain all the nonlinearity required for a problem by adding hidden processing elements without introducing excess complexity. Many weights that come

with the addition of each new hidden processing element may not be required or even helpful for the modeling task at hand. These excess weights tend to make the network fit the idiosyncrasies or "noise" of the data and thus fail to generalize well to new cases. This problem, known as overfitting, typically arises because of an excess of weights.

Weight decay is a method of developing a neural network that minimizes overfitting without sacrificing the predictive power of the model. This method initially provides the network with all the nonlinearity it needs by providing a large number of hidden processing elements. Subsequently, it decays all the weights to varying degrees so that only the weights that are necessary for the approximation task remain. Two central premises are employed: 1) when given two models of equivalent performance on a training data set, favor the smaller model; and 2) implement a cost function that penalizes complexity as part of the backpropagation algorithm. The network is trained by minimizing this cost function. Complexity is only justified as it expresses information contained in the data. A weight set that embodies all or almost all of the information in the data and none of the noise will maximize generalizability and performance.

The cost function is constructed by introducing a "decay term" to the usual error function used to train the network. It is designed to optimize the model so that the network captures all the important information in the training set, but does not adapt to noise or random characteristics of the training set. In view of these requirements, the cost function must take into account not only prediction error, but also the significance of model weights. A combination of these two terms yields an objective function which, when minimized, generalizes optimally. Performing a conventional gradient descent with this objective function optimizes the model.

In introducing the decay term, an assumption is made about what constitutes information. The goal is to choose a decay term that accurately hypothesizes the prior distribution of the weights. In finding a good prior distribution, one examines the likelihood that the weights will have a given distribution without knowledge of the data.

Weigend et al, "Generalization by Weight-Elimination with Application to Forecasting", in *Advances in Neural Information Processing Systems* 3, pp. 875-82, and incorporated herein by reference, discloses the following cost function for weight decay:

$$\frac{1}{2} \sum_{k \in D} (\text{target}_k - \text{output}_k)^2 + \lambda \sum_{i \in W} \frac{\omega_i^2 / \omega_o^2}{1 + \omega_i^2 / \omega_o^2} \quad (\text{Eq. 1})$$

where:

D is the data set;

target_k is the target, or desired, value for element k of the data set;

output_k is the network output for element k of the data set;

λ represents the relative importance of the complexity term;

W is the weight set;

ω_i is the value of weight i; and

ω_o is a constant that controls the shape of the curve that penalizes the weights.

The first term of the Weigend function measures the performance of the network, while the second term measures the complexity of the network in terms of its size. With this

cost function, small weights decay rapidly, while large weights decay slowly or not at all.

A major failing of the Weigend cost function, and similar weight decay schemes, is that they do not accurately mimic the intended prior distribution. Finding a good prior distribution (or "prior") is a key element to developing an effective model. Most of the priors in the literature are sufficient to demonstrate the concept of weight decay but lack the strengths required to accommodate a wide range of problems. This occurs because the priors tend to decay weights evenly for a given processing element, without sufficiently distinguishing important weights (which contain more information) from unimportant weights (which contain less information). This often results either in 1) undesired decaying of important weights, which diminishes the power of the system to accommodate nonlinearity, or 2) undesired retention of excess unimportant weights, which leads to overfitting.

The present invention uses the following improved cost function, which addresses the above problems:

$$\frac{1}{2} \sum_{k \in D} (\text{target}_k - \text{output}_k)^2 + g\lambda \sum_{i \in W} \left(c_i \omega_i^2 - \frac{1}{1 + |\omega_i|} \right) \quad (\text{Eq. 2})$$

where g represents a new term known as the interlayer gain multiplier for the decay rate, and c_i is a constant. The interlayer gain multiplier takes into account the relative proximity of the weights to the input and output ends of the network. Thus, the interlayer gain multiplier allows application of the decay term with greater potency to elements that are closer to the inputs, where the majority of the weights typically reside, while avoiding excessive decay on weights corresponding to elements closer to the outputs, which are more critical, since their elimination can effectively sever large numbers of input-side weights.

By intensifying decay on input-side elements, the cost function of Equation 2 improves the ability of model development component 801 to decay individual weights while preserving processing elements containing valuable information. The result is that weak interactions are eliminated while valid interactions are retained. By retaining as many processing elements as possible, the model does not lose the power to model nonlinearities, yet the overfitting problem is reduced because unnecessary individual weights are removed.

Once the cost function has been iteratively applied to the network, weights that have been decayed to a very small number (defined as ε) are removed from the network. This step, known as "thresholding the net" is performed because it is often difficult to completely decay weights to zero.

Once the network has been trained using past data, the network's model definition is stored in data files. One portion of this definition, called the "CFG" file, specifies the parameters for the network's input variables, including such information as, for example, the lengths of the variables, their types, and their ranges. Referring now to FIG. 21, there is shown a portion of a typical CFG file, specifying parameters for an ACCOUNT variable 2101 (representing a customer account number) and a PAUDYMDY variable 2102 (a profile variable representing the ratio of transaction days divided by the number of days in the month).

The file formats used to store the other model definition files for the network are shown below.

ASCII File Formats

The ASCII network data files (.cta, .sta, .lca, .wta) consist of tokens (non-whitespace) separated by whitespace (space, tab, newline). Whitespace is ignored except to separate tokens. Use of line breaks and tabs is encouraged for clarity, but otherwise irrelevant.

File format notation is as follows:

- * Bracketed text denotes a token.
- * Nonbracketed text denotes a literal token which must be matched exactly, including case.
- * Comments on the right are not part of the file format; they simply provide further description of the format.
- * In the comments, vertical lines denote a block which can be repeated. Nested vertical lines denote repeatable sub-blocks.

Weights values for a slab and class are stored as a one-dimensional array, but conceptually are indexed by two values—PE and interconnect within PE. The values are stored in row-major order, as exemplified here.

Transaction Processing Component 802

Once the model has been created, trained, and stored, fraud detection may begin. Transaction processing component 802 of system 100 preferably runs within the context of a conventional authorization or posting system for customer transactions. Transaction processing component 802 reads current transaction data and customer data from databases 805, 806, and generates as output fraud scores representing

the likelihood of fraud for each transaction. Furthermore, transaction processing component 802 can compare the likelihood of fraud with a predetermined threshold value, and flag transactions for which the threshold is exceeded.

The current transaction data from database 805 typically includes information such as: transaction dollar amount; date; time (and time zone if necessary); approve/decline code; cash/merchandise code; available credit (or balance);

credit line; merchant category code; merchant ZIP code; and PIN verification (if applicable).

The customer data from database 806 typically includes information from three sources: 1) general information on the customer; 2) data on all approved or declined transactions in the previous seven days; and 3) a profile record which contains data describing the customer's transactional pattern over the last six months. The general information on the customer typically includes information such as: customer ZIP code; account open date; and expiration date. The profile record is a single record in a profile database summarizing the customer's transactional pattern in terms of moving averages. The profile record is updated periodically (usually monthly) with all of the transactions from the period for the customer, as described below.

System 100 can operate as either a batch, semi-real-time, or real-time system. The structure and processing flow of each of these variations will now be described.

Batch System: FIG. 14 shows operation of a batch system. Transactions are recorded throughout the day or other convenient period 1402. At the end of the day, the system performs steps 1403 to 1409 for each transaction. It obtains data describing the current transaction 1403, as well as past transaction data, customer data, and profile data 1404. It then applies this data to the neural network 1405 and obtains a fraud score 1406. If the fraud score exceeds a threshold 1407, the account is flagged 1408. In the batch system, therefore, the transaction which yielded the high fraud score cannot itself be blocked; rather, the account is flagged 1404 at the end of the day so that no future transactions are possible. Although the batch system does not permit immediate detection of fraudulent transactions, response-time constraints may mandate use of the batch system in some implementations.

Semi-Real-Time System: The semi-real-time system operates in a similar manner to the batch system and uses the same data files, but it ensures that no more than one high-scoring transaction is authorized before flagging the account. In this system, as shown in FIG. 15, fraud likelihood determination is performed (steps 1504 to 1509) immediately after the transaction is authorized 1503. Steps 1504 to 1509 correspond to steps 1403 to 1409 of the batch system illustrated in FIG. 14. If the likelihood of fraud is high, the account is flagged 1509 so that no future transactions are possible. Thus, as in the batch system, the current transaction cannot be blocked; however, the semi-real-time system allows subsequent transactions to be blocked.

Real-Time System: The real-time system performs fraud likelihood determination before a transaction is authorized. Because of response-time constraints, it is preferable to minimize the number of database access calls when using the real-time system. Thus, in this embodiment, all of the customer information, including general information and past transaction data, is found in a single record of profile database 806. Profile database 806 is generated from past transaction and customer data before the transaction processing component starts operating, and is updated after each transaction, as described below. Because all needed data are located in one place, the system is able to retrieve the data more quickly than in the batch or semi-real-time schemes. In order to keep the profile database 806 current, profile records are updated, using moving averages where applicable, after each transaction.

Referring now to FIG. 16, there is shown a flowchart of a real-time system using the profile database. Upon receiving a merchant's request for authorization on a transaction 1602, the system obtains data for the current transaction

1603, as well as profile data summarizing transactional patterns for the customer 1604. It then applies this data to the stored neural network model 1605. A fraud score (representing the likelihood of fraud for the transaction) is obtained 1606 and compared to a threshold value 1607. Steps 1601 through 1607 occur before a transaction is authorized, so that the fraud score can be sent to an authorization system 1608 and the transaction blocked by the authorization system if the threshold has been exceeded. If the threshold is not exceeded, the low fraud score is sent to the authorization system 1609. The system then updates customer profile database 806 with the new transaction data 1610. Thus, in this system, profile database 806 is always up to date (unlike the batch and semi-real-time systems, in which profile database 806 is updated only periodically).

Referring now to FIG. 12, there is shown the method of creating a profile record. The system performs the steps of this method when there is no existing profile record for the customer. The system reads the past transaction database 1101 for the past six months and the customer database 1103 (steps 1202 and 1203 respectively). It generates a new profile record 1204 with the obtained data and saves it in the profile database 1205. If there are more accounts to be processed 1206, it repeats steps 1202 through 1205.

Referring now to FIG. 13, there is shown the method of updating an existing profile record. The system reads the past transaction database 1101 for the past six months, customer database 1103 and profile database (steps 1302, 1303, and 1304 respectively). It combines the data into a single value for each variable in the profile database. This value is generated using one of two formulas.

For variables that represent average values over a period of time (for example, mean dollars of transactions in a month), Equation 3 is used:

$$\text{newProfData} = ((1-\alpha) * \text{oldProfData}) + (\alpha * \text{currentVal}) \quad (\text{Eq. 3})$$

For variables that represent extreme values over a period of time (for example, highest monthly balance), Equation 4 is used:

$$\text{newProfData} = \max(\text{currentVal}, \beta * \text{oldProfData}) \quad (\text{Eq. 4})$$

In Equations 3 and 4:

newProfData is the new value for the profile variable;
oldProfData is the old value for the profile variable;
currentVal is the most recent value of the variable, from the past transaction database; and

α and β are decay factors which are used to give more importance to recent months and less importance to months further in the past.

The value of β is set so that older data will "decay" at an acceptable rate. A typical value for β is 0.95.

The value of α is generated as follows: For the batch and semi-realtime systems, α is set to a value such that the contribution of the value from more than six months previous is nearly zero. For profiles that have been in existence for at least six months, the value of α is $1/6$. For newer profiles, the value is $1/(n+1)$, where n is the number of months since the profile was created. For the real-time system, profile updates do not occur at regular intervals. Therefore, α is determined using the following equation:

$$\alpha = 1 - \exp(-t/T) \quad (\text{Eq. 5})$$

where:

t is the time between the current transaction and the last transaction; and

T is a time constant for the specific variable.

Furthermore, for the real-time system, currentVal represents the value of the variable estimated solely using information related to the current transaction and the time since the last transaction, without reference to any other historical information.

Once the new values for the profile variables have been generated, they are placed in an updated profile record 1305 and saved in the profile database 1306. If there are more accounts to be processed 1307, the system repeats steps 1302 through 1306.

In all of these embodiments, the current transaction data and the customer data are preferably pre-processed to derive fraud-related variables which have been empirically determined to be effective predictors of fraud. This is done using the same technique and the same fraud-related variables as described above in connection with neural network training.

Referring now to FIGS. 17 through 19, there are shown flowcharts illustrating the operation of the preferred embodiment of the transaction processing component. Some of the individual elements of the flowchart are indicated by designations which correspond to module names. The following brief description summarizes the processing.

Referring now to FIG. 17, there is shown the overall operation of transaction processing component 802. First the system runs module CINIT-NET 1702, which initializes network structures. Then, it runs module CSCORE 1703. Module CSCORE 1703 uses current transaction data, data describing transactions over the past seven days, a profile record, and customer data to generate a fraud score indicating the likelihood that the current transaction is fraudulent, as well as reason codes (described below). The system then checks to see whether there are more transactions to be processed 1704, and repeats module CSCORE 1703 for any additional transactions. When there are no more to be processed, the system runs module FREENET 1705, which

frees the network structures to allow them to be used for further processing.

Referring now to FIG. 18, there is shown the operation of module CSCORE 1703. First, module CSCORE 1703 obtains current transaction data, data describing transactions of the past seven days, the profile record, and customer data (steps 1802 through 1805). From these data, module CSCORE 1703 generates the fraud-related variables 1806 described above. Then, it runs module DeployNet 1807, which applies the fraud-related variables to the stored neural network and provides a fraud score and reason codes. CSCORE then outputs the score and reason codes 1808.

Referring now to FIG. 19, there is shown the operation of module DeployNet 1807. Module DeployNet 1807 first scales the fraud-related variables 1902 to match the scaling previously performed in model development. If the value of a variable is missing, DeployNet sets the value to equal the mean value found in the training set. Then it applies the scaled variables to the input layer of neural network 108, in step 1903. In step 1904, it processes the applied data through the network to generate the fraud score. The method of iterating the network is well known in the art.

In addition to providing fraud scores, in step 1904, module DeployNet 1807 optionally generates "reason codes". These codes indicate which inputs to the model are most important in determining the fraud score for a given transaction. Any technique that can track such reasons may be used. In the preferred embodiment, the technique set forth in co-pending U.S. application Ser. No. 07/814,179, (attorney's docket number 726) for "Neural Network Having Expert System Functionality", by Curt A. Levey, filed Dec. 30, 1991, the disclosure of which is hereby incorporated by reference, is used.

The following module descriptions summarize the functions performed by the individual modules.

FALCON C FILES

FILE NAME: CINITNET

DESCRIPTION: Contains code to allocate and initialize the network structures.

FUNCTION NAME: CINITNET()

DESCRIPTION: Allocate and initialize the network structures.

FILE NAME: CSCORE

DESCRIPTION: Generates fraud related variables and iterates the neural network.

FUNCTION NAME: SCORE()

DESCRIPTION: Creates fraud related variables from raw variables

and make calls to initialize the input layer and iterate the neural network.

FUNCTION NAME: setInput()

DESCRIPTION: Sets the input value for a processing element in the input layer.

FUNCTION NAME: hiReason()

DESCRIPTION: Finds the three highest reasons for the score.

FILE NAME: CFREENET

DESCRIPTION: Makes function calls to free the network structures.

FUNCTION NAME: CFREENET()

DESCRIPTION: Frees the network structures.

FILE NAME: CCREATEP

DESCRIPTION: Contains the cardholder profile creation code.

FUNCTION NAME: createpf()

DESCRIPTION: Creates a profile record for a cardholder using the previous month's authorizations and cardholder data.

FILE NAME: CUPDATEP

DESCRIPTION: Updates a profile of individual cardholder activity.

FUNCTION NAME: updatepf()

DESCRIPTION: Updates a profile record for a cardholder using the previous profile record values as well as the previous month's authorizations and cardholder data

FILE NAME: CCOMMON

DESCRIPTION: This file contains functions which are needed by at least two of the

FALCON C FILES

following: creatpf(), updatepf(), score().
 FUNCTION NAME: accumMiscCnts()
 DESCRIPTION: Increments counters of various types for each authorization found.
 FUNCTION NAME: accumSicCnts()
 DESCRIPTION: Increments SIC variable counters.
 FUNCTION NAME: initSicCounts()
 DESCRIPTION: Initializes the SIC variable counters.
 FUNCTION NAME: updateSicMovAvgs()
 DESCRIPTION: Updates the SIC profile variables.
 FUNCTION NAME: writeMiscToProfile()
 DESCRIPTION: Writes various variables to the profile record after they have been calculated.
 FUNCTION NAME: hncDate()
 DESCRIPTION: Converts a Julian date to a date indicating the number of days since Jan 1, 1990.
 FUNCTION NAME: missStr()
 DESCRIPTION: Checks for "missing" flag (a period) in a null terminated string. String must have only blanks and a period to qualify as missing. A string with only blanks will also qualify as "missing".

Cascaded Operation

One way to improve system performance is via "cascaded" operation. In cascaded operation, more than one neural network model is used. The second neural network model is trained by model development component 801 in a similar manner to that described earlier. However, in training the second model, model development component 801 uses only those transactions that have fraud scores, as determined by prior application to the first neural network model, above a predetermined cascade threshold. Thus, the second model provides more accurate scores for high-scoring transactions. While the same fraud-related variables are available to train both models, it is often the case that different variables are found to be significant in the two models.

Referring now to FIG. 20, there is shown a flowchart of the operation of the transaction processing component in a cascaded system. First, transaction processing component 802 scores each transaction using the first model 2002, as described above. Those transactions that score above the cascade threshold 2003 are applied to the second neural network model 2005. The system outputs scores and reason codes from either the first model 2004 or the second model 2006, as appropriate.

The above-described cascading technique may be extended to include three or more neural network models, each having a corresponding cascade threshold.

Performance Monitor

The system periodically monitors its performance by measuring a performance metric comprising the fraud detection rate and the false positive rate. Other factors and statistics may also be incorporated into the performance metric. When the performance metric falls below a predetermined performance level, the system may either inform the user that the fraud model needs to be redeveloped, or it may proceed with model redevelopment automatically.

From the above description, it will be apparent that the invention disclosed herein provides a novel and advantageous method of detecting fraudulent use of customer accounts and account numbers, which achieves high detection rates while keeping false positive rates relatively low. The foregoing discussion discloses and describes merely exemplary methods and embodiments of the present invention. As will be understood by those familiar with the art, the invention may be embodied in many other specific forms without departing from the spirit or essential characteristics

thereof. For example, other predictive modeling techniques besides neural networks might be used. In addition, other variables might be used in both the model development and transaction processing components.

Accordingly, the disclosure of the present invention is intended to be illustrative of the preferred embodiments and is not meant to limit the scope of the invention. The scope of the invention is to be limited only by the following claims.

What is claimed is:

1. In a computer having a processor and storage, a computer-implemented process for detecting a fraudulent transaction in a customer account, comprising the steps of:
 - obtaining past transaction data for processing by the computer
 - pre-processing the past transaction data to derive past fraud related variables;
 - generating a predictive model with the processor from the past fraud related variables;
 - storing a representation of the predictive model in the computer storage;
 - receiving current transaction data for processing by the processor;
 - receiving customer data for processing by the processor; and
 - generating a computer signal indicative of the likelihood of fraud in the current transaction, wherein the processor generates the computer signal by applying the current transaction data and the customer data to the stored predictive model.
2. The computer-implemented process of claim 1, wherein the step of obtaining customer data comprises accessing a computer database containing general customer data and a computer database containing customer transactional pattern data.
3. The computer-implemented process of claim 1, wherein the step of obtaining customer data comprises accessing no more than one profile computer database record containing customer transactional pattern data.
4. The computer-implemented process of claim 3, wherein the profile computer database record further contains general customer data.
5. The computer-implemented process of claim 1, wherein the current transaction data and the customer data

each comprise a plurality of elements and the computer processes each element by:

- determining a relative contribution of the element to the determined likelihood of fraud;
- determining from each relative contribution thus determined a reason code value; and
- generating a computer signal indicative of the reason code value.

6. The computer-implemented process of claim 1, further comprising the steps of:

- comparing the computer signal indicative of the likelihood of fraud with a preset threshold value; and
- responsive to the computer signal exceeding the preset threshold value, generating a computer signal indicating fraud.

7. The computer-implemented process of claim 1, further comprising the iterative steps of:

- determining a cascade threshold value;
- comparing the computer signal indicative of the likelihood of fraud with the cascade threshold value; and
- responsive to the computer signal exceeding the cascade threshold value, generating another computer signal indicative of the likelihood of fraud in the current transaction by applying the current transaction data and the customer data to another predictive model.

8. The computer-implemented process of claim 1, further comprising the steps of:

- monitoring a performance metric of the computer generated predictive model, wherein the processor monitors the performance metric;
- comparing the performance metric with a predetermined performance level; and
- generating and storing a new predictive model from past transaction data responsive to the performance level exceeding the performance metric, wherein the new predictive model is generated by the processor and stored in the computer storage.

9. the computer-implemented process of claim 8, wherein the performance metric comprises:

- a fraud detection rate measurement; and
- a false positive rate measurement.

10. The computer-implemented process of claim 1, further comprising the steps of:

- pre-processing the current transaction data to derive current fraud-related variables; and
- pre-processing the customer data to derive customer fraud-related variables;
- wherein the computer signal representing the likelihood of fraud is generated responsive to application of the current fraud-related variables and the customer fraud-related variables to the stored predictive model.

11. The computer-implemented process of claim 10, wherein the past fraud-related variables and the current fraud-related variables each comprise at least:

- factors obtained from data referring to transaction dollar amounts related to fraud;
- factors obtained from data referring to transaction dates and times related to fraud;
- factors obtained from data referring to transaction approvals and declines related to fraud; and
- factors obtained from data referring to risk groups related to fraud.

12. The computer-implemented process of claim 10, wherein the past fraud-related variables and the current fraud-related variables each comprise at least:

factors obtained from data referring to customers related to fraud; and

factors obtained from data referring to merchants related to fraud.

13. The computer-implemented process of claim 10, further comprising the steps of, for each variable in the set of derived current fraud-related variables and derived customer fraud-related variables:

- determining a relative contribution of the variable to the determined likelihood of fraud;
- determining from each relative contribution thus determined a reason code value; and
- generating a computer signal indicative of the reason code value.

14. A computer-implemented process for detecting fraud for a transaction on a customer account, comprising the steps of:

- obtaining past transaction data for processing by the computer;
- pre-processing the past transaction data to derive past fraud-related variables;
- training a neural network on the computer with the derived past fraud-related variables;
- storing the neural network in storage associated with the computer;
- obtaining current transaction data for processing by the computer;
- pre-processing the current transaction data to derive current fraud-related variables;
- obtaining customer data for processing by the computer;
- pre-processing the customer data to derive customer fraud-related variables; and
- generating a computer signal representing the likelihood of fraud responsive to application of the current fraud-related variables and the customer fraud-related variables to the stored neural network.

15. In a computer having a processor and storage, a computer-implemented process of training a neural network, the neural network for predicting fraudulent transactions in a customer account based on selected data, the neural network being represented on the computer and stored in the computer storage and comprising a plurality of interconnected processing elements, each processing element comprising:

- a plurality of inputs;
- a plurality of weights, wherein each weight is associated with a corresponding input by the processor to generate weighted inputs;
- means for combining the weighted inputs; and
- a transfer function for processing the combined weighted inputs on the processor to produce an output;
- the training process comprising the iterative steps of:
 - applying input data to the neural network to generate output data, wherein the processor applies the input data to the neural network and generates the output data;
 - comparing the generated output data to a desired output, wherein the processor performs the comparison;
 - adjusting operation of the neural network responsive to the results of the comparing step; and
 - after the iterative steps of applying, comparing, and adjusting, storing the neural network in the computer storage.

35

16. The computer-implemented process of claim 15, wherein the step of adjusting operation of the neural network comprises the substeps of:

selecting a subset of the weights to be decayed; and
decaying the selected subset of weights.

17. The computer-implemented process of claim 16, wherein the substep of selecting a subset of the weights to be decayed comprises applying and minimizing a cost function including an interlayer gain multiplier which varies a decay rate responsive to the location of a weight within the network.

18. The computer-implemented process of claim 17, wherein the cost function is of the form:

$$\frac{1}{2} \sum_{k \in D} (\text{target}_k - \text{output}_k)^2 + g\lambda \sum_{i \in W} \left(c_1 \omega_i^2 - \frac{1}{1 + |\omega_i|} \right),$$

wherein:

D represents a data set;

target_k represents a target value for element k of the data set;

output_k represents a network output for element k of the data set;

g represents the interlayer gain multiplier;

λ represents the relative importance of the complexity term;

W represents a weight set;

ω_i represents a value of weight i; and

c₁ represents a constant.

19. A system for detecting a fraudulent transaction in a customer account, comprising:

a computer processor for executing programmed instructions and for storing and retrieving data;

program memory, coupled to the processor, for storing program instruction steps for execution by the processor;

a predictive model component, coupled to the processor, for determining the likelihood of a fraudulent transaction;

past transaction data storage, coupled to the processor, for receiving, storing, and sending past transaction data;

a model development component, coupled to the processor, for training the predictive model based on the past transaction data in accordance with program instructions in the program memory and executed by the processor, thereby generating a trained predictive model;

current transaction data storage, coupled to the processor, for receiving, storing, and sending current transaction data;

customer data storage, coupled to the processor, for receiving, storing, and sending customer data; and

an output device, coupled to the processor, for outputting a computer signal indicative of the likelihood of fraud in a transaction, wherein the processor generates the computer signal in accordance with program instructions in the program memory and executed by the processor, said computer signal being responsive to the application of the current transaction data and the customer data to the trained predictive model.

20. The system of claim 19, wherein the model development component derives past fraud-related variables as a function of the past transaction data, and said past fraud-related variables are used to train the predictive model.

36

21. The system of claim 19, wherein:

the predictive model component comprises a neural network, coupled to the processor; and

the model development component trains the neural network based on the past transaction data in accordance with program instructions in the program memory and executed by the processor, thereby generating a trained neural network;

wherein the processor generates the computer signal by applying the current transaction data and the customer data to the trained neural network.

22. The system of claim 19, further comprising:

a past transaction data pre-processor, coupled to the processor, for deriving past fraud-related variables from the past transaction data;

wherein the model development component trains the predictive model based on the past fraud-related variables in accordance with program instructions in the program memory and executed by the processor, thereby generating the trained predictive model;

a current transaction data pre-processor, coupled to the processor, for deriving current fraud-related variables from the current transaction data; and

a customer data pre-processor, coupled to the processor, for deriving customer fraud-related variables from the customer data;

wherein the processor generates the computer signal by applying the current fraud-related variables and the customer fraud-related variables to the trained predictive model.

23. In a system for detecting fraud in a transaction on an account belonging to a customer, the system including a computer processor for executing programmed instructions and for storing and retrieving data, a computer readable memory storing thereon:

a neural network, coupled to the processor, for determining the likelihood of a fraudulent transaction;

past transaction data storage, coupled to the processor, for receiving, storing, and sending past transaction data;

a past transaction data pre-processor, coupled to the processor, for deriving past fraud-related variables from the past transaction data;

a model development component, coupled to the processor, for training the neural network based on the past fraud-related variables, thereby generating a trained neural network;

current transaction data storage, coupled to the processor, for receiving, storing, and sending current transaction data;

a current transaction data pre-processor, coupled to the processor, for deriving current fraud-related variables from the current transaction data;

customer data storage, coupled to the processor, for receiving, storing, and sending customer data; and

a customer data pre-processor, coupled to the processor, for deriving customer fraud-related variables from the customer data;

wherein the processor generates a computer signal indicative of the likelihood of fraud in a transaction, said computer signal being responsive to the application of the current fraud-related variables and the customer fraud-related variables to the trained neural network.

24. In a computer-controlled transaction processing system including predictive modeling means for receiving

current transaction data, processing the current transaction data, and outputting a plurality of output values, including a score value representing a likelihood of a fraudulent transaction, an improved computer-implemented process for identifying and determining fraudulent transaction data, comprising the steps of:

prior to receiving the current transaction data for at least one current transaction;

generating a consumer profile for each of a plurality of consumers from a plurality of past fraud-related variables and from consumer data, each consumer profile describing historical spending patterns of a corresponding consumer, the past fraud-related variables being derived by pre-processing past transaction data, the past transaction data including values for a plurality of transaction variables for a plurality of past transactions, the consumer data including values for each consumer for a plurality of consumer variables;

training the predictive modeling means with the consumer profiles and with the past fraud-related variables to obtain a predictive model; and

storing the obtained predictive model in the computer; receiving current transaction data for a current transaction of a consumer;

receiving consumer data associated with the consumer; receiving the consumer profile associated with the consumer;

pre-processing the obtained current transaction data, consumer data, and consumer profile to derive current fraud-related variables for the current transaction;

determining the likelihood of fraud in the current transaction by applying the current fraud-related variables to the predictive model; and

outputting from the predictive modeling means an output signal indicating the likelihood that the current transaction is fraudulent.

25. The computer-implemented process of claim 24, wherein the generating step comprises the substeps of:

receiving past transaction data for a plurality of past transactions, the past transaction data providing values for a plurality of transaction variables;

receiving consumer data for each of a plurality of consumers, the consumer data providing values for a plurality of consumer variables for each consumer;

pre-processing the past transaction data to derive past fraud-related variables wherein at least some of the past fraud-related variables are not present in the plurality of variables in the past transaction data; and

generating a consumer profile for each consumer from the past fraud-related variables and the received consumer data, each consumer profile describing historical spending patterns of the consumer.

26. The computer-implemented process of claim 24, further comprising the step of updating the received consumer profile with the received current transaction data.

27. The computer-implemented process of claim 24, wherein the step of training the predictive modeling means comprises the substeps of:

applying the consumer profile and the derived past fraud-related variables to the predictive modeling means;

ranking output data from the predictive modeling means as a function of a quality measurement;

adjusting the predictive modeling means as a function of the ranking step; and

repeating the applying, ranking, and adjusting steps until the quality measurement exceeds a predetermined level indicating that the predictive modeling means is adequately trained.

28. The computer-implemented process of claim 27, wherein the step of training the neural network comprises the substeps of:

applying the consumer profile and the derived past fraud-related variables to the neural network;

ranking output data from the neural network as a function of a quality measurement;

adjusting the neural network as a function of the ranking step; and

repeating the applying, ranking, and adjusting steps until the quality measurement exceeds a predetermined level indicating that the neural network is adequately trained.

29. The computer-implemented process of claim 24, wherein the step of training the predictive modeling means comprises training a neural network organized as a plurality of input processing elements for receiving the plurality of data values in the transaction data, a plurality of hidden processing elements coupled to the input processing elements for processing the transaction data, and a plurality of output processing elements coupled to the hidden processing elements for outputting the plurality of output values.

30. The computer-implemented process of claim 29, wherein the neural network comprises a plurality of processing elements linked by connections characterized by weights, and the step of adjusting the predictive model comprises the steps of:

selecting a subset of the weights to be decayed; and

decaying the selected subset of weights.

31. The computer-implemented process of claim 30, wherein the substep of selecting a subset of the weights to be decayed comprises applying and minimizing a cost function including an interlayer gain multiplier which varies a decay rate responsive to the location of a weight within the network.

32. The computer-implemented process of claim 31, wherein the cost function is of the form:

$$\frac{1}{2} \sum_{k \in D} (\text{target}_k - \text{output}_k)^2 + g\lambda \sum_{i \in W} \left(c_i \omega_i^2 - \frac{1}{1 + |\omega_i|} \right),$$

wherein:

D represents a data set;

target_k represents a target value for element k of the data set;

output_k represents a network output for element k of the data set;

g represents the interlayer gain multiplier;

l represents the relative importance of the complexity term;

W represents a weight set;

w_i represents a value of weight i; and

c_i represents a constant.

33. The computer-implemented process of claim 24, wherein the current transaction data, the consumer profile, and the consumer data each comprise a plurality of data elements, further comprising the steps of, for at least one of the data elements:

determining a relative contribution value of the data element to the output signal indicating the likelihood that the current transaction is fraudulent;

39

determining a reason code as a function of the relative contribution value;
 retrieving an explanation associated with the determined reason code value; and
 outputting a computer signal indicative of the reason code and the explanation.

34. The computer-implemented process of claim 24, further comprising the steps of:

monitoring a performance metric of the predictive modeling means, the performance metric comprising at least one of a fraud detection rate measurement and a false positive rate measurement;

comparing the performance metric with a predetermined performance level for the performance metric; and responsive to the predetermined performance level exceeding the performance metric, repeating the step of training the predictive modeling means.

35. The computer-implemented process of claim 24, wherein the past fraud-related variables and the current fraud-related variables each comprise at least:

transaction dollar amounts of past transactions;
 transaction dates and times of past transactions;
 transaction approvals and declines of past transactions;
 risk groups of past transactions; and
 merchants of past transactions.

36. In a computer system comprising:

a computer-readable memory; and

a neural network stored in the computer readable memory, the neural network comprising a plurality of interconnected processing elements, each processing element being in a layer of the neural network, each layer having a distance to an input layer, each processing element comprising:

a plurality of inputs (x);

a plurality of weights (w), each weight w associated with a corresponding input (x) to form weighted inputs;
 a summation function for combining the weighted inputs; and,

a transfer function for processing the combined weighted inputs into an output (z);

an improved computer-implemented process for training the neural network characterized by:

iteratively decaying the weights of at least one processing element by a cost function that varies a decay rate for decaying the weights by a function of the distance of the input layer from the layer containing the processing element.

37. The computer-implemented process of claim 36, wherein the cost function is of the form:

$$\frac{1}{2} \sum_{k \in D} (\text{target}_k - \text{output}_k)^2 + g\lambda \sum_{i \in W} \left(c_i \omega_i^2 - \frac{1}{1 + |\omega_i|} \right)$$

wherein:

D represents a data set;

target_k represents a target value for an element k of the data set;

output_k represents a neural network output for element k of the data set;

40

g represents an interlayer gain multiplier that varies as a function of the distance between the input layer and the layer containing the processing element;

l represents the relative importance of the decay rate term;

W represents a weight set;

w_i represents a value of weight i; and

c₁ represents a constant.

38. In a computer-controlled transaction processing system including predictive modeling means for receiving current transaction data, processing the current transaction data, and outputting a plurality of output values, including a score value representing a likelihood of a fraudulent transaction, an improvement for identifying and determining fraudulent transaction data, comprising:

a model development component for developing a predictive model, comprising:

means for receiving past transaction data for a plurality of past transactions, the past transaction data providing values for a plurality of transaction variables;

means for receiving consumer data for each of a plurality of consumers, the consumer data providing values for a plurality of consumer variables for each consumer;

means for pre-processing the past transaction data to derive past fraud-related variables wherein at least some of the past fraud-related variables are not present in the plurality of variables in the past transaction data;

means for generating a consumer profile for each individual consumer, from the past fraud-related variables and the received consumer data, the consumer profile describing historical spending patterns of the consumer;

means for training the predictive model with the consumer profiles and with the past fraud-related variables; and

means for storing the trained predictive model in the computer; and

a model application component, for applying the trained predictive model, comprising:

means for receiving current transaction data for a transaction of a consumer;

means for receiving consumer data associated with the consumer;

means for receiving the consumer profile associated with the consumer;

a current transaction data pre-processor, for pre-processing the obtained current transaction data, consumer data, and consumer profile to derive current fraud-related variables for the current transaction;

means for determining the likelihood of fraud in the current transaction by applying the current fraud-related variables to the predictive model; and

means for outputting from the predictive model an output signal indicating the likelihood that the current transaction is fraudulent.

[57] **ABSTRACT**

An automated system and method detects fraudulent transactions using a predictive model such as a neural network to evaluate individual customer accounts and identify potentially fraudulent transactions based on learned relationships among known variables. The system may also output reason codes indicating relative contributions of various variables to a particular result. The system periodically monitors its performance and redevelops the model when performance drops below a predetermined level.
